## Problem

Scenario: A wildlife conservation organization is studying the impact of eucalyptus tree density on the population of koalas in a particular region. They have collected data on the number of eucalyptus trees per hectare and the corresponding koala population density in different areas within the region.

Using the provided data, perform linear regression analysis to model the relationship between eucalyptus tree density and koala population density. Determine the equation of the best-fit line and interpret the slope and y-intercept of the line in the context of the scenario. Use the regression model to predict the koala population density in an area with a specific eucalyptus tree density (provided by the user).
